x = (\frac{1}{2}) \frac{1}{2} \frac{1}{2}

Computing the correlation of the variable (8) = 645

Introduction to Probability Standard

Probability is a beanch of matchenatics that cleals with the likelihood of events occursing. It avantities uncertainty sanging from O (smpossible) to I (certain) bey concepts include experiments, outcomes, events (and probability rules. It is widely used in statistics, finance, science and every day decision making.

D Symmetrical Outcomes:

· Example: A fair coin tas a 50%. clance of landing on teads or tails. A six sided die has a 1/6 chance for cach number

(2) Frequentist Approach

· Probability is based on long term relative frequency.

Example: It it ruined 62% of the post Joo,000 days inseattle, the probability of air tomorrow is extinated at 0.62. He word, this approach become toicky when considering changing weather condition.

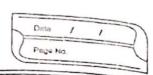

(3) Subjective Poobability Probability is based on pressoral belief or opinion Example predicting an election outcome leg Ms opinion vatles then an objective probability. Basic Poobability Concepts

1 Poobability of a single Event when all outcomes are equally likely, the probability of an event occurring is Probability - Number of Savourable Outcomes
Total Number of Possible atterns Example: Polling a die

. A six sided die hos six posible octtones
i.o. (173,4,5,6) i.e. (1,7,3,4,5,6) Probability of rolling a I: 1/6
Probability of rolling a 2006: 2/6 = 1/3 Probability of Two idependent trents Both Ocurring Example : Politing Two dice and getting & sum ob 6 There are 36 possible outcomes when volling too dre Favorable out cones for a sum of 6 (1,5),(2,4),(3,3),(4,7) (5,7) -) 5(66 Probability 5136 Probability of an Event Not Gaussing

To P(A) is the probability of an event occurring, he

Probability of it is not occurring is

Example: Reling two dice and Not getting a sind of
Probability of ralling a 6 is 5/36 Probability of not rolling a 6: 1-5/36 I Definition of Independent Events Two events, A and B are Independent if the public Of Bacussing romains the same regardless of whother A OCCUEL. Example: Tossing a fair coin twice.

Probability of heads on the second toss remins

1/2, whether the first toss was heads or take. · Independent Elents I First tors is leads 2 Second toss is Leads example of Non Independent Fronts · Rain in Houston us pain in Calleston
. It it sains in Houston, it is more likely to roin in reasty Calleston 2 Psobability of Both Events Occising (A and B)

If A and B are independent, the probability of

both occurring is

DIXIVERS P(A and B) = P(X) X P(B) Sample loin dip & Polling a six sided die Cheads and gettig?

Pleads ($^{2}/2$) Prolling ($^{2}/2$) = $^{1}/6$ Pleads and Polling ($^{2}/2$) = $^{2}/2 \times ^{1}/6$ = $^{2}/2 \times ^{1}/2$

3 Probability of Eitles Event Occurring (A or B)

For andependent events, the probability that oitles

A or B Happens is

P(A or B) = P(A) + P(B) - P(A and B)

Example: Rolling a die & Flipping a loin (volling a 6 or Hads) $P(6) = \frac{1}{16} \quad P(\text{Heads}) = \frac{1}{12} \quad P(6 \text{ and Heads}) = \frac{1}{12} \quad P(6 \text{ or Heads}) = \frac{1}{12} \quad P(6 \text{ and Heads})$ $= \frac{1}{16} + \frac{1}{2} - \frac{1}{12} \quad P(6 \text{ and Heads})$

Sometimes, its easier to calculate the probability of an arent not occurring and subtract from J

Example: Rolling a die those files (at least one voll is a I)

probability of not rolling a I in a single throw

P(rot 1): I - I - 5

6

Probability of at loast one roll boing a I
I-175 - 91
